Service Manual

GX3000U

Sixty-Four-Channel Thirty-Five-Watt UHF/FM Transceiver

This manual is intended for use by qualified technicians and includes all necessary information pertaining to GX3000U operation, installation, circuit design, and Maintenance. Information on the installation of the TN22 and TN23 tone board is also included. Changes which occur after the printed date will be incorporated in supplemental service publications.

The complete GX3000U transceiver model numbers are:

- GX3000UAA111
- GX3000UAA131
- GX3000UAA141
- GX3000UAA151

Channel Spread	+5 MHz

General Information

2

2.1 DESCRIPTION

The Standard Communications Corp. (SCC) GX3000U is a semiduplex UHF/FM mobile transceiver that incorporates operator-programmable priority scan. Frequencies for each of 64 channels may be programmed into the GX3000U EPROM. A temperature compensating circuit provides frequency stabilization over -30°C to +60°C.

The scanning function looks for a signal on any of the channels programmed for scanning. If a priority channel is programmed, the scanning starts with this channel. If no priority channel is programmed, scanning starts with the displayed channel.

The following features may be programmed into the EPROM:

- busy channel lockout
- one priority channel
- up to 37 discrete EIA CTCSS tone frequencies (when TN22 is installed)
- time out timer with programmable time ranging from 0.5 min to 7.5 min in increments of .5 min
- channel frequencies

The priority channel may be changed by the operator, and scan channels are programmable by the operator.

A back-up feature permits operator programmed channels and the working channel to be retained in memory when the power is off. If back-up is not in effect, the unit powers up to channel one.

The EPROM is programmed by SCC or the dealer. An EPROM Burner (A3400) is available for programming the EPROM. EPROM's may be reprogrammed numerous times after they are erased.

2.2 OPTIONS

Options available for use with the GX3000U include:

A00416006.....	Tower Clamp for AT26 & AT27
AR1.....	Accessory Receptacle Kit
AT10.....	UHF 5 dB Gain Antenna
AT27.....	UHF 8.25 dB Gain Antenna
AT56.....	UHF 4.5 dB Gain Antenna
BM1.....	Mobile Mount
BST-1.....	Base Station Tray
CM1.....	Cowl Mount
MM1.....	Magnetic Mount
MP600.....	Base Station Microphone
MP502.....	Telephone Type Microphone; black or white (used with PH506B)
PH506B.....	Hanger for MP502 with PC Switch; black
RCU-1.....	Remote Control Unit
REU-1.....	Remote Extension Unit
RTU-51A.....	Remote Terminal Unit
TM1.....	Trunk Mount
TN22.....	CTCSS Multiple Tone Board
TN23.....	CTCSS Single Tone Board
UG-1186/U.....	Antenna Connector
WW1.....	1/4 Wave Whip Antenna
12/120-12.....	12 Amp Power Supply
201S.....	7 Watt Extension Speaker; brown, grey or white

All necessary service information for each of these devices is included separately with each unit.

FCC Information

3

The GX3000U complies with the Federal Communications Commission (FCC) requirements that regulate Business Radio Service and other services within the 450 to 512 MHz range. The user must know and comply with all applicable part of the FCC Rules and Regulations. Rules applicable to each service may be ordered from:

SUPERINTENDENT OF DOCUMENTS
Government Printing Office
Washington, D.C. 20402

A valid station license and call sign are required before operating the GX3000U. It is the user's responsibility to apply for and obtain an FCC radio license. The following data pertaining to the GX3000U will be included on the FCC license application.

Type Accepted FCC Parts 21, 90 and 95
Output Power 35 watt
Emission 16F3
Frequency Range 450 to 512 MHz
Type Number APV9T22883

Controls & Connections

4

5.1 FCC REQUIREMENTS

FCC regulations require that the transceiver's deviation and frequency be tested before initial installation or operation. Before conducting the following procedure, conduct the performance test in the Maintenance Section of this manual.

5.2 PROCEDURE

1. The transceiver can be mounted at any angle. Choose a location to mount the transceiver that allows:

- accessibility to front panel controls
- connections to a power source and an antenna
- nearby space for installation of a microphone hanger

2. The front panel of the GX3000U may be positioned in one of two positions. The normal position, tilted upward, is for installation on or below the dash. For overhead installation, the following steps invert the front panel to allow viewing of the controls and display:

- a. Remove four screws from each side of the transceiver.
- b. Remove the top and bottom covers.
- c. Two screws on each side attach the front panel to the transceiver. Remove these screws.
- d. Invert the front panel position.
- e. Attach the front panel using the screws removed in Step c.
- f. Attach the top and bottom covers using the screws removed in Step a.
- g. Install the transceiver in an inverted position so that the front panel is tilted downward.

3. Mount the bracket using the washers, nuts, and long hex head bolts.

4. Thread the mylar washers onto the mounting bracket knobs.
5. Position the transceiver within the bracket arms, matching the bracket and transceiver notches to effect the desired positioning.
6. Secure the transceiver to the brackets with the mounting knobs.
7. At the rear of the transceiver, connect the antenna cable to the antenna jack (see Figure 2).
8. Connect the red power cord to a suitable DC source (13.6 VDC $\pm 20\%$, 10 amp current). Connect the black power cord to negative ground. See Figure 2 for this step.
9. Use a through line wattmeter to confirm that the voltage/standing-wave ratio is 1.5 to 1 or better.

Figure 2. GX3000U Installation Interconnections

5.3 OPTIONAL INSTALLATIONS

The GX3000U also accepts tone boards TN22 and TN23.

- TN22 is a multi-tone tone board capable of separate tones for each channel.
- TN23 is a single-tone tone board having one tone for all channels.

To use a CTCSS tone board, the following three steps are necessary:

1. Reprogram the EPROM.
2. Install the tone board.
3. Unsolder a jumper.

The following instructions describe installation and alignment for both tone boards. Refer to Figure 3 for the installation location.

Figure 3. Tone Board Installation

5.3.1 TN22 Tone Board

A. Installation

1. Remove the transceiver top and bottom cover.
2. Install the TN22 in the following manner.
 - a. Ensure that the tone board is installed in such a way that it is sitting atop the transceiver shield bracket (see Figure 3) with the component side up.

- b. Hook the TN22 tone board to the hook at point A so that the model number end can be screwed onto the tab at point B (see Figure 3).
 - c. With a 2.6 mm self-tapping screw, secure the model end of the tone board to the tab at point B (see Figure 3).
 - d. Plug the 9-pin socket into transceiver plug JL09.
 - e. Plug the 5-pin socket into transceiver plug JR04.
 - f. Plug the white wire from TN22 into socket YB06 of white wire from the radio.
3. On the component side (top of radio) of the GX3000 series, unsolder "Flying Joint" JR10. JR10 is located near the 8-pin connector JR01.

NOTE: The frequency must be programmed by the EPROM, (FX10) in radio.

B. Encoder Alignment

1. Connect the test equipment as shown in Figure 4.
2. Select any programmed CTCSS channel.
3. Set the tone generator to the desired frequency.
4. Set the communications monitor to the radio transmitter frequency.
5. Key the transmitter and ensure that the Lissajous figure in the communications monitor is a stationary circle.
6. Key the transmitter and adjust R106 on the tone board until the tone deviation is ± 650 Hz.

C. Decoder Alignment and Test

1. If the GX3000 MON LED is on, depress the MON key until the MON LED turns off.
2. Set the communications monitor to the receive frequency of the radio.
3. Modulate the signal with the desired tone frequency, with a deviation of ± 500 Hz.
4. Set the signal generator output to the "OFF" position.

5. Connect the hang up button on the rear of the microphone to ground. Audible noise should disappear.
6. Gradually increase the RF signal level. The tone squelch opening level should not exceed 10 dB QS.

Figure 4. Tone Board Encoder Alignment

5.3.2 TN23

A. Installation

1. Remove the transceiver top and bottom cover.
2. Install the TN23 in the following manner.
 - a. Ensure that the tone board is installed in such a way that it is sitting atop the transceiver shield bracket (see Figure 3).
 - b. Hook the TN23 tone board to the hook at point A so that the model number end can be screwed onto the tab at point B (see Figure 3).
 - c. With a screw, secure the model number end to the tab at point B (see Figure 3).
 - d. Plug in the 9-pin socket into the transceiver plug JL09.
 - e. Plug in the 5-pin socket into the transceiver plug JR04.
3. On the component side (top of radio) of the GX3000 series, unsolder "Flying Joint" JR10. Refer to Figure 7.
4. Use the six DIP switches on TN23 to program the tone frequencies (see Figure 16).

NOTE: If the tone board is installed in the radio, the EPROM (FX10) must be programmed to accept tone board installation/operation in receive mode.

5. For programmed tones in the frequency range of 67 thru 120 Hz, cut RA25 on the tone board. RA25 is located near QA02 at end of 8-pin IC TL062.

B. Encoder Alignment and Decoder Test.

1. Connect the test equipment as shown in Figure 12.
2. Set the communications monitor to the radio transmitter frequency.
3. Key the transmitter and adjust R07 until the tone deviation is ± 650 Hz.
4. If the MON LED is on, push the MON key until the MON LED turns off.
5. Set the communications monitor to the receive frequency of the radio.
6. Modulate the signal with the desired tone frequency, with a deviation of ± 500 Hz.
7. Set the signal generator output to the "OFF" position.
8. Connect the hang up button on the rear of the microphone to ground. Audible noise should disappear.
9. Gradually increase the RF signal generator level. The tone squelch opening level should not exceed 10 dB QS.

Figure 5. Tone Board Decoder Test

1. Ensure the following connections are made:

- The power cord with a 10 amp fuse is connected to the power source.
- The antenna is connected to the jack marked "ANT" on the back of the unit.
- The MP566 Microphone is connected to the 5-prong jack on the left side of unit.

2. Rotate OFF/VOLUME control clockwise to ON.

3. Select the desired channel using the UP and DOWN keys as follows:

- Press the UP key to select the next higher channel.
- Press the DOWN key to select the next lower channel.
- Channel selection automatically steps while the UP or DOWN key is held depressed. Selection stops when key is released.

NOTE: If the selected channel is the priority channel, the dot labeled "P" will light.

4. Adjust the ON/VOLUME control to the desired volume of received signals.

5. With no signal present, rotate the SQUELCH control clockwise until the background noise just disappears.

FEATURES

Priority Channel

Program a channel as the priority channel as follows:

- Select desired channel as in Step 3.
- Press the PRI key.
- Program the channel as a scan channel (see Scan Channels).

A channel which has been programmed as a priority channel may be disabled as follows:

- Select the priority channel as in Step 3.
- Press the PRI key to disable the priority status of the channel.

Back Up

The back up feature enables the working channel and the operator-programmed priority and scan channels to be retained in memory when the power is turned off. Back up is in effect when the SQL key has not been turned counterclockwise past the click to the BACK UP OFF position.

Scan Channels

Program scan channels as follows:

- Select the desired channel as in Step 3.
- Press the MEMO key.
- Pressing the MEMO key again returns the channel to normal, non-scan status.
- Repeat this procedure for each channel to be programmed as a scan channel.

Scanning

To use the scan feature, the squelch must be set as in step 5, there must be no signal present, and the microphone must be hung up. The scan mode is then entered by pressing the SCAN key. The channel display will be blank, and the dot labeled "S" will blink. Scanning then proceeds in one of the following two modes:

a) Regular scan (no priority channel is programmed):

Scanning starts with the lowest channel and proceeds sequentially through channels selected as scan channels until a signal is encountered.

When a signal is encountered, the busy channel is displayed and scanning stops.

b) Priority scan (priority channel is programmed):

Scanning starts with priority channel.

If a signal is detected in the priority channel, scanning stops.

If no signal is detected in the priority channel:

- Other scan channels are scanned alternately with priority channel.

- The priority channel continues to be scanned even when the scanning stops on a channel other than the priority channel.

If the working channel is no longer busy, scanning begins again.

All keys except the CLR key are disabled during scanning.

Taking the microphone off its hanger will stop scanning, but scan mode will not be exited.

Scan mode is exited when the CLR key is pressed or the transmitter is keyed.

Clear

The CLR key operates as follows:

- When in scan mode, pressing CLR exits scan mode.
- When current channel is other than priority channel, pressing CLR again recalls the priority channel. An additional push at this point returns to the previous channel.

Priority Scan

In priority scan mode, the time spent sampling the busy channel and the time spent scanning are as follows:

- Without tone board:
 - Stay at working channel for 1,000 milliseconds.
 - Scan priority channel for 50 milliseconds.
- With tone board:
 - Stay at working channel for 1000 milliseconds.
 - Scan priority channel for 300 milliseconds.

Monitor

It is illegal to transmit on a channel without first monitoring it. A channel is monitored as follows:

- If a tone frequency is programmed for the channel:

lift the microphone off the bracket

or

press the MON key to suppress the tone frequency and monitor the channel.

- Press MON again to mute audio and reinstate the tone frequency.
- If no tone frequency is programmed for the channel:

- Monitoring is continuous.

Display Brightness

The brightness of channel display can be controlled by the DIM key. There are three levels of brightness, and the GX3000U powers up to the brightest level. Pressing the DIM key dims the brightness by one step.

- If DIM is pushed when display is at the dimmest level, display defaults to the brightest level.

LED Indicators

The LED Indicators function as follows:

- S is lit during scanning mode.
- P is lit during priority scanning or when the current channel is the priority channel.
- TX is lit during transmission. When programmed for time-out timing, the time out timer stops transmission when the time limit has been reached, and the TX light is off.
- MON

If CTCSS is programmed for the channel:
MON is lit when the MON key is pushed and channel monitoring is in progress.

If CTCSS is not programmed for the channel:
MON is lit during RX mode.

- BUSY is on when the channel status is busy, without regard to CTCSS tone presence.
- CALL is used for applications as required.

Time out timer

If the time out timer feature is programmed:

- A beeping alarm sounds 10 seconds before the transmitting time limit.
- Transmission is cut off when this limit has been reached.
- Timer is reset by releasing push-to-talk button momentarily.

Refer to the transceiver block diagram (Figure 6) and the schematics at the rear of the manual for the following description.

7.1 PLL FREQUENCY SYNTHESIZER

Follow the block diagram in Figure 6 for this section.

7.1.1 Reference Signal

The output of the 6.4 MHz reference oscillator circuit QP03 is divided by QP01 to produce a 12.5 kHz reference signal.

The oven circuit provides heat compensation for crystal XP01 in order to prevent the frequency drift when the temperature is low. Frequency drift is kept within ± 5 ppm.

7.1.2 VCO

The oscillation frequency of the VCO is controlled by the voltage applied to QV03. The VCO output is divided according to the pulse swallow counter created by QP02 and QP01, corresponding to the channel frequency.

7.1.3 N Number

QP01 contains the N number. This number is the frequency set in the EPROM. It is serially transferred to QP01.

7.1.4 Phase Detector

The phase detector in QP01 compares the divided VCO frequency with the reference frequency. If these two frequencies are in phase, the DC correction voltage from QP01 to the VCO remains constant. If the divided frequency is lower than the reference frequency, the DC correction voltage from QP01 is increased. If the divided frequency is greater than the reference frequency, the DC correction voltage is decreased.

7.1.5 VCO Correction

The correction voltage travels through QP32 to QV03. The capacitance of QV03 varies indirectly with the DC correction voltage.

7.1.6 Phase-Locked-Loop

The VCO output then travels through the phase-locked-loop circuit again and again. The loop becomes locked when the reference frequency matches the divided frequency from the VCO.

7.2 RECEIVER

The receiver uses a double conversion superheterodyne to operate in the frequency range 450 to 512 MHz.

7.2.1 RF Stage

The incoming RF signal passes through the antenna and is amplified by RF AMP QR03. The amplified signal passes on to the gate of the first mixer QR04 to be mixed with the first local oscillator.

7.2.2 First Local Oscillator

The VCO originates the first local oscillator. The first local oscillator from the VCO passes through LP62 and LP63 and is applied to the gate of the first mixer QR04.

7.2.3 First Intermediate Frequency (IF)

The heterodyning action of the first mixer produces a 45 MHz intermediate frequency (first IF) which is fed through a bandpass filter (LR33 and LR34), passed through two two-pole crystal filters (FR30 and FR31), and amplified by the first IF AMP (QR31 and QR33).

7.2.4 Second Local Oscillator

Crystal XP50 generates a second local oscillator signal of 45.455 MHz. This is applied to the base of the second mixer QR50.

7.2.5 Second Mixer, Second IF

The signal from the first IF AMP is applied to the base of QR50 and heterodyned with the signal from the second local oscillator. A second IF of 455 KHz is produced and passed through ceramic filters FR50 and FR51.

The second IF is then applied to QR56 and passed through QR56's internal detector circuit to recover the audio.

7.2.6 Volume Control and AF Amplifier

The detected signal, passed through the de-emphasis circuit (CR80 and RR63), is amplified by AF PREAMP QA03 and applied to AF volume control RG01. The AF signal which passed through RG01 is amplified by AF AMP QA01. This signal drives speaker NG01.

7.2.7 Squelch Circuit

The signal for the squelch circuitry is obtained from QR56, detected by QR54 and QR55, and applied to squelch control RG02. This DC voltage controls a switch in QR56 which in turn controls QA04 to disable AUDIO PREAMP QA03.

7.3 TRANSMITTER

The transmitter delivers 35 watts in the frequency range of 450 to 512 MHz.

7.3.1 Microphone Amplifier

The audio signal from the microphone travels through QM01. QM01 and associated circuitry constitute a pre-emphasis characteristic microphone amplifier.

7.3.2 Filter and Attenuator

The amplified signal then proceeds through additional circuitry of QM01 where it is limited and passed through a roll-off filter. The signal from QM01 is amplified by AMP QP32 (1/2) and then travels through the FET attenuator QP33.

7.3.3 RF Signal

Next, the signal is applied to the VCO, and then directly to the 6.4 MHz REF circuit to obtain a modulated signal.

7.3.4 RF Amplifier

The output from the VCO is output to the pre-amp stage and is amplified by QT01, QT02, and QT03. QT01 through QT03 are controlled by TX +8V. This TX +8V is synchronized to the PLL unlock circuit. This circuit prevents transmission when it is unlocked.

7.3.5 Power Module

The signal amplified by QT03 is amplified by the power module QB01 and further amplified by QB02. The QB01 output is controlled by APC +B to maintain constant RF output power.

7.3.6 Automatic Power Control (APC)

The RF output power is sampled by CB35, rectified by QB04, and applied to APC control RC04. This voltage is applied to QC04, QC05, and QC06 to control the supply voltage on Driver QB01, maintaining constant power output.

As the temperature of QB01 and QB02 increases, the resistance of posistor QB07 increases. The voltage that flows to QB01 and QB02 decreases.

7.3.7 SWR Protector Circuit

QB05 rectifies any reflected power caused by antenna mismatch. This rectified power is applied to QC03 and then passes on to the APC circuit. RC02 adjusts the maximum SWR level before the RF power is reduced.

23

The FCC requires that the deviation and frequency of the transceiver be checked annually.

The inherent quality of the solid-state components used in this transceiver provide many years of continuous use. Take the following precautions to prevent damage to the transceiver.

- Never key the transmitter unless an antenna or suitable dummy load is connected to the transceiver's antenna receptacle.
- Ensure that the input voltage does not exceed 16 VDC or fall below 11 VDC.
- During alignment, do not transmit for more than 10 seconds at a time. Transmitting over longer periods can cause heat build-up and transistor damage.

- Performance test: conducted to check overall transceiver operation. This should be performed before transceiver sale/installation.

- **Alignment:** conducted if the transceiver fails the performance test or if a critical electrical component has been replaced. SCC recommends that alignment be performed whenever maintenance is performed.
- **Troubleshooting:** conducted after alignment to isolate a fault in the transceiver.

The following test equipment, or its equivalent, is necessary for GX3000U maintenance.

EQUIPMENT	MODEL
FM Communications Monitor (service monitor)	Cushman CE-6A
RF Wattmeter with 50 load	Bird 6154
Tone Generator	Cushman CE-11
Voltmeter	Hewlett Packard 427A
RF Probe	Hewlett Packard 11096B
Frequency Counter	Hewlett Packard 5314A
Oscilloscope	Hewlett Packard 1220A
DC Ampere Meter	Simpson 374
Power Supply	Adjustable 11 to 13.6V, 25 Amp

The GX3000U alignment points are shown in Figure 8. After connecting the test equipment, ensure that the supply voltage is 13.6 V.

Figure 7. GX3000U Alignment Points

8.5.1 PLL

Connect the test equipment as illustrated in Figure 8.

1. Connect a voltmeter with an internal resistor greater than 500 k ohm to CV14.
2. Set the transceiver to a programmed channel, and key the PTT (push to talk button).
3. Adjust CV08 so that the voltage at CV14 in the TX mode is 3.5 V.
4. Unkey the PTT.
5. Adjust CV04 so that the voltage at CV14 is 3.5 V.
6. Repeat Steps 2 through 5.
7. Connect a frequency counter to TP02.
8. Adjust CP09 so that the indicated frequency is 45 MHz below the frequency of the programmed channel selected in Step 2.

8.5.2 Transmitter

1. Connect the test equipment as illustrated in Figure 8.

2. Connect an RF power meter and a dummy load to the antenna connector of the unit, and depress the PTT switch.
3. Set the power supply voltage to 11.0 V.
4. Turn RC02 and RC04 fully clockwise.
5. Adjust CV04 so that the voltage at CV14 is 3.5 V.
6. Change the power supply voltage to 13.6 V and repeat Step 5.
7. Adjust RC04 so that output power is 37.0 W.
8. Connect a linear detector and dummy load to the antenna connector of the transceiver.

NOTE: Attach a capacitor (10 uF/16 V) between the audio generator and Mic connector pin 1, with the "+" side connected to the transceiver.

9. Set the signal generator to 2 MHz above the frequency of a programmed channel.
10. Turn RP24 fully counter clockwise and set the audio generator output to 50 mV.
11. Using RP24, adjust the deviation to ± 4.5 kHz.

Figure 8. TX/PLL Test Setup

12. Turn RP24 clockwise until a deviation of ± 4.5 kHz is again attained.
13. Lower the audio generator output by 20 dB, and use RP44 to adjust for minimum distortion.
14. Adjust the audio generator output to produce a deviation of ± 3 kHz.
15. Increase the audio generator output by 20 dB, and use RP24 to adjust to a deviation of ± 4.5 kHz.
16. Repeat Steps 13 through 15.

8.5.3 Receiver

1. Connect the test equipment as illustrated in Figure 9.
2. Connect a signal generator to the antenna connector.
3. Connect a 4 dummy load, an RF voltmeter, and an oscilloscope to the external speaker jack.

4. Connect a 30 uA meter to TP01.
5. Set the AF volume to the center position.
6. Adjust LR52, LR33, LR34, LR35, and LR36 for maximum noise on the AC voltmeter.
7. Set the signal generator to a programmed channel frequency with a deviation of ± 5 kHz.
8. Set the transceiver to a programmed channel.
9. Apply the signal from the signal generator to the transceiver.
10. Adjust CR01, CR02, CR09, CR12, CR15, CR16, CR69, CR70, LR33, LR34, LR35, and LR36 for maximum meter deflection at TP01.

NOTE: Ensure that the signal generator output is lowered below the meter's saturation level.

11. Repeat Step 10 several times.
12. Adjust the AF volume to approximately 1 V.
13. Adjust LR52 for maximum reception waveforms.

Figure 9. RX Test Setup

When the front end range is 10 MHz, perform the following additional steps:

14. Set the signal generator and the transceiver channel to a frequency near, but above, the low edge.
15. Apply a signal from the signal generator to the transceiver.
16. Adjust CR12 and CR16 for maximum meter deflection at TP01.
17. Ensure that the highest frequency still meets the specifications. If it does not, repeat Steps 14 through 17, using a slightly higher frequency for Step 14.

8.6 PERFORMANCE TEST

8.6.1 Microprocessor

Many of the features unique to the GX3000 are governed by the microprocessor. The program written for the microprocessor controls the following functions:

- o channel display
- o transmit and receive frequencies
- o priority scan
- o tone encode and decode frequencies

Perform the following steps to test these functions.

1. Connect a 50 ohm dummy load to the antenna receptacle.
2. Turn on the off/volume control. Confirm that the channel display illuminates showing either the lowest channel or the priority channel (if the priority channel is programmed).
3. Press the UP button several times. Confirm that the channel number increases one step each time the UP button is depressed.
4. Press the UP button and hold it depressed. Confirm that the channel numbers increase at a rate of approximately 6 ch per second.
5. Repeat Steps 3 and 4 for the DOWN button.
6. Ensure that the squelch control is in the Back up, off position. Make note of the current channel.
7. Turn the off/volume control off and then on. If the current channel is Step 6 was the priority channel, the transceiver must power up to the priority channel. Otherwise, the transceiver must power up to channel 1.
8. Press the MON key. If a tone board is installed, the audio must be muted.
9. Press the MON key again. If a tone board is installed, Ensure that the audio returns.
10. Depress the DIM button. Confirm that the display illumination level changes. There are three levels of illumination.
11. Depress the PRI button once. If the current channel is not on the EPROM priority channel, the "P" indicator must illuminate. Depress the PRI button a second time and confirm that the "P" indicator goes out.
12. Depress the MEMO button. Confirm that the "S" indicator illuminates.
13. Depress the MEMO button a second time. Confirm that the "S" indicator goes out.
14. Enter several channels into scan memory by depressing the MEMO button while stopped on each of several different channels.
15. Ground the microphone hanger to the chassis.
16. Set the squelch fully clockwise.
17. Depress the SCAN button. The "S" indicator must start blinking and the channel display must go blank. This indicates that scanning is taking place.
18. Unground the microphone. The transceiver must stop scanning. The "S" indicator must stop blinking and remain on. The channel display must show the channel that was being scanned when the microphone was ungrounded.
19. Ground the microphone. The transceiver must start scanning.
20. Depress the CLR button. Scanning must stop.

21. Depress the SCAN button. Confirm that the display is blank and that the "S" indicator starts blinking. This indicates that scanning is taking place.
22. Unground the microphone. Confirm that scanning stops.
23. Depress the PTT button on the microphone. The TX light must illuminate.
24. Ground the microphone hanger. Confirm that the transceiver stays on the channel that was transmitted on.
25. Unground the microphone hanger and press the PTT button. Confirm the following:
 - The radio beeps 10 seconds before the timer duration is reached.
 - The radio stops transmitting when the timer duration is reached.

8.6.2 Transmitter

1. Connect a wattmeter with a 50 ohm dummy load to the antenna receptacle.
2. Turn on the off/volume control.
3. Key the transmitter and confirm the following:
 - The minimum power output is 35 watts.
 - The TX indicator illuminates.
 - The receiver background audio turns off.
4. Set the service monitor to a programmed channel frequency.
5. Key the transmitter. Confirm that the service monitor indicates a transmit frequency within ± 500 Hz.
6. Set the service monitor to measure the transmitter deviation.
7. Key the transmitter. Speak into the microphone. Confirm that the deviation does not exceed ± 4.5 kHz.
8. Repeat Steps 3 through 7 for all other programmed channels.

8.6.3 Receiver

1. Connect the signal generator output of a service monitor to the transceiver's antenna receptacle.
2. Connect an AC voltmeter to the external speaker jack with a 4 ohm, 5 watt resistor in parallel.
3. Turn the squelch control fully counterclockwise.
4. Adjust the volume control for a voltmeter reading of 1.4 VAC.
5. With modulation turned off, set the service monitor's signal generator to the receive frequency of the selected programmed channel.
6. Slowly increase the signal level until the voltmeter reading is reduced to 0.14 VAC (20 dB decrease). Confirm that the service monitor's signal generator output does not exceed 0.5 uV.
7. Reduce the service monitor's signal generator output to zero.
8. Adjust the squelch control clockwise until the static just disappears (threshold squelch).
9. Set the internal modulation of the service monitor's signal generator to ± 3 kHz, with a 1 kHz audio tone.
10. Increase the service monitor's signal generator output until audio is regained. Confirm that the signal generator output does not exceed 0.35 uV.
11. Turn the squelch control fully clockwise (tight squelch).
12. Increase the service monitor's signal generator output until audio is regained. Confirm that the service monitor's signal generator output does not exceed 3.5 uV.
13. Repeat Steps 5 through 12 for other all programmed channels.

Drawings

9

The drawings in this section show the electrical and mechanical parts locations and interconnections of the GX3000U. The values of most electrical parts are indicated on the schematic diagrams.

Parts List

10

10.1 GENERAL

Information on most electrical and mechanical parts is included in the parts lists. The parts are listed by reference designators in alphanumeric order.

10.2 ORDERING REPLACEMENT PARTS

Crystal orders should be referred to the Frequency Management Department at (213) 532-5300 ext. 251, or write:

Standard Communications Corp.
Frequency Management Department
P.O. Box 92151
Los Angeles, CA 90009-2151

All other parts orders should be referred to the Parts Department at (213) 532-5300 ext. 248 or write:

Standard Communications Corp.
Parts Department
P.O. Box 92151
Los Angeles, CA 90009-2151

Please note that SCC may not be able to fill replacement parts orders without such identifying information as:

- reference designator
- value
- description
- part number
- unit model number

Resistors

Unless otherwise noted, all chip resistors in this parts list are valued at 1/10 W, $\pm 5\%$. All resistance values are in ohms. Resistors not listed in this parts list are composed of carbon film and valued at 1/4 W, $\pm 5\%$. The resistance values of those resistors not listed are on the schematic diagram.

GX3000 Memory Backup Installation

There is an orange wire now installed in the GX3000 series transceiver. The purpose of this wire is to connect the memory backup power to the transceiver. This will hold all programmed data in memory even if the radio is turned off. This orange wire should be installed to a fused constant D.C. source under the dashboard (such as the lights).

If the orange wire is connected to the battery, an in-line fuse should be installed as close to the battery as possible.

GX3000U Service Information Insert

The following paragraph replaces the information in Step 5 from Section 5.3.2, A on page 7 of the GX3000U Owner's Operating and Maintenance Manual. The specified frequency range has changed.

5. For programmed tones in the frequency range of 67 through 120 Hz, cut RA25 on the tone board. RA25 is located near QA02 at end of 8-pin IC TL062.
